Introduction

Context

With the help of the configuration tool, it is possible to locate and change the values of different configuration options. By being able to understand the results of the modifications made by the tool, the integration of the configuration is validated.

Objective

Compare the results of the configuration based on the changes made by the tool.

Hypothetical case

Let's suppose that the default configuration has been highly modified. Let's also assume that the bootloader was built using this configuration and programmed onto the board. You restart the board and find that the system does not boot. The last time you powered on the board, the system booted successfully, but this time it did not. One might think that the cause of the problem is the recently modified configuration.

Questionnaire

- How can you revert the changes in the configuration if you do not remember exactly which configuration option(s) were modified and led to the system being unable to boot successfully?

If you were lucky enough to save a copy of the original config file at another location, you can simply copy that file to the location where the modified one is and with the same name. Using the following command `cp path/to/original-file path/to/modified-file`, Also you can use `make oldconfig` this would update the config file taking a provided `.config` as a base

- How can I restore the default state of a modified configuration?

As I said previously, if you have a copy you can use that, if not, you can use `make defconfig` to generate a config file with the default values.

Information needed to solve this problem

- Is there a copy of the previous working configuration file.
- location of the copy of the previous working configuration file.
- Board that you're using.
- Version of U-Boot being used.

Comparison between config files

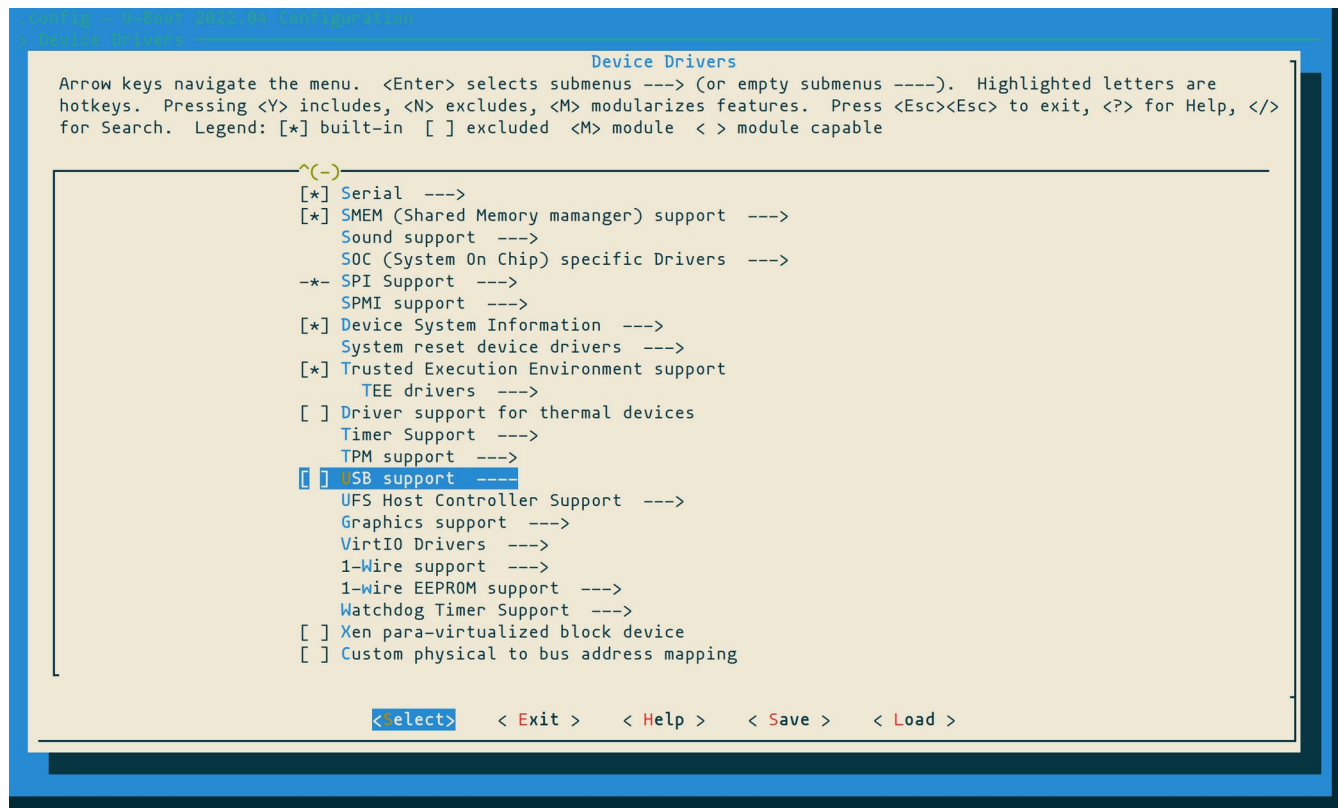

Defconfig

For the creation of the default config file, we utilize the following command

```
make ARCH=arm defconfig
```

Modified defconfig

For the modification of the config file generated in the previous step, we utilized the command `make ARCH=arm menuconfig` to access the configuration menu and locate the CONFIG_USB option and disable it.

Comparison between config files

Once the config file was modified, we proceeded to do a comparison between the default and modified. During this we found that most the configurations related to the USB were deleted, and the remaining ones were set as disabled. Also, there were no other configurations modified.

```
CONFIG_CMD_USB=y                                ➡ # CONFIG_CMD_TSI148 is not set
# CONFIG_CMD_USB_SDP is not set                  ➡ # CONFIG_CMD_UNIVERSE is not set
# CONFIG_CMD_USB_MASS_STORAGE is not set         ➡ # CONFIG_CMD_USB_SDP is not set
```

```
CONFIG_DFU=y
CONFIG_DFU_OVER_USB=y
CONFIG_DFU_WRITE_ALT=y
# CONFIG_DFU_TFTP is not set
# CONFIG_DFU_TIMEOUT is not set
# CONFIG_DFU_MMC is not set
# CONFIG_DFU_RAM is not set
CONFIG_DFU_SF=y
CONFIG_DFU_SF_PART=y
# CONFIG_DFU_VIRT is not set
# CONFIG_SET_DFU_ALT_INFO is not set
CONFIG_SYS_DFU_DATA_BUF_SIZE=0x800000
CONFIG_SYS_DFU_MAX_FILE_SIZE=0x800000

#
# DMA Support
#
CONFIG_DMA=y
CONFIG_DMA_CHANNELS=y
CONFIG_SANDBOX_DMA=y
# CONFIG_DMA_LPC32XX is not set
# CONFIG_TI_EDMA3 is not set
# CONFIG_DMA_LEGACY is not set

#
# Fastboot support
#
CONFIG_FASTBOOT=y
# CONFIG_USB_FUNCTION_FASTBOOT is not set
CONFIG_UDP_FUNCTION_FASTBOOT=y
CONFIG_UDP_FUNCTION_FASTBOOT_PORT=5554

CONFIG_DFU=y
CONFIG_DFU_WRITE_ALT=y
# CONFIG_DFU_TFTP is not set
# CONFIG_DFU_TIMEOUT is not set
# CONFIG_DFU_MMC is not set
# CONFIG_DFU_RAM is not set
CONFIG_DFU_SF=y
CONFIG_DFU_SF_PART=y
# CONFIG_DFU_VIRT is not set
# CONFIG_SET_DFU_ALT_INFO is not set
CONFIG_SYS_DFU_DATA_BUF_SIZE=0x800000
CONFIG_SYS_DFU_MAX_FILE_SIZE=0x800000

#
# DMA Support
#
CONFIG_DMA=y
CONFIG_DMA_CHANNELS=y
CONFIG_SANDBOX_DMA=y
# CONFIG_DMA_LPC32XX is not set
# CONFIG_TI_EDMA3 is not set
# CONFIG_DMA_LEGACY is not set

#
# Fastboot support
#
CONFIG_FASTBOOT=y
CONFIG_UDP_FUNCTION_FASTBOOT=y
CONFIG_UDP_FUNCTION_FASTBOOT_PORT=5554
CONFIG_FASTBOOT_BUF_ADDR=0
```

[illegible]

U-Boot Compilation with modified config file

Configuration update and makefile creation

All the update of the configuration and build of the new makefiles, it's being done at the very beginning of the setup

```
CFG      u-boot.cfg
UPD      include/generated/timestamp_autogenerated.h
ENVC     include/generated/env.txt
ENVP     include/generated/env.in
ENVTEXT  include/generated/environment.h
```

Compilation

Once the new configuration is loaded, and makefiles are generated, the compilation starts

```
HOSTCC   scripts/basic/fixdep
CC        lib/asm-offsets.s
CC        arch/arm/lib/asm-offsets.s
```

Linking

Once the compilation is done, starts the linking

```
HOSTLD   tools/gen_ethaddr_crc
```

Object generation

Once the linking it's done, starts generating Object files

```
HOSTCC tools/mkenvimage.o
HOSTCC tools/os_support.o
```

Images generation

Unfortunately, we couldn't generate the images because a missing make file

```
scripts/Makefile.build:54: arch/arm/cpu/sandbox/Makefile: No such file or directory
make[1]: *** No rule to make target 'arch/arm/cpu/sandbox/Makefile'. Stop.
make: *** [Makefile:1894: arch/arm/cpu/sandbox] Error 2
```

Conclusions

The possibility of changing the configuration for each build that we perform it's a powerful tool, but as it is powerful it can be a complete disaster. If you change a configuration without knowing what it's related to, it can make you unable to compile the project as it happened to me. Also, if this happens, there might be no documentation about it or it might be difficult to locate.
